Subject: Question regarding 08/901612...

Applicants in this case have amended the claims to add new sequence identifiers. The newly added sequences are variants of sequences already in the claims for example: original SEQ ID NO: 7 in the claim has the sequence agagatgattaggcagaggt

newly added SEQ ID NO: 58 in the claim has the sequence

agagatgauuaggcagaggt.

SEQ ID NO: 58 definitely has a similar structure as SEQ ID NO: 7, would the search for SEQ ID NO: 7 pick up hits that read on SEQ ID NO: 58?

Thanks.

Janet L. Epps-Ford, Ph.D.

The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides containing a sequence which is complementary to at least two non-contiguous regions of an HBV nucleic acid, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection.
                                                                                                                                                                                                                                                                      Location/Qualifiers

            The present sequence represents a synthetic oligonucleotide HBV43Ma which is complementary to a portion of the hepatitis B virus (HBV) RMA. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides containing a sequence which is complementary to at least two non- contiguous regions of an HBV nucleic acid, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Single-stranded DNA probe comprising an anti-target nucleic acid, a (-)-
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 comprising in 3'-5' order, an anti-target nucleic acid segment, a (-)-
promoter segment functionally linked to the anti-target segment, and a
nucleic acid reporter segment. The probe is useful for testing a sample
of a nucleic acid for the presence of a target nucleic acid segment or
for detecting a target nucleic acid segment in a sample. The probe may
also be used for the detection of hepatitis B virus (HBV). The present
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    which is used in an example from the present invention. The specification describes a composition of magnetic glass particles, which contain at least one magnetic object with a mean diameter between 5-500 nm. The composition is useful for the purification of nucleic acids. The composition can be used to process large quantities of nucleic acid samples, because it does not involve the particles being centrifuged or the fluids being drawn through glass fiber filters. PCR primers AAH25415-16 were used to amplify HBV DNA fragments. The amplified fragment can be

Synthetic

```
The present sequence represents a synthetic oligonucleotide HBV-87b which contains a sequence which is complementary to at least two non-contiguous regions of a hepatitis B virus (HBV) nucleic acid. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides complementary to a portion of the HBV RNA, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                                                                                                     Oligo:nucleotide(s) complementary to hepatitis B virus (HBV) sequences used in the detection and treatment of HBV infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    a

                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The present sequence represents a synthetic oligonucleotide HBV88b which is complementary to a portion of the hepatitis B virus (HBV) RNA. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides containing a sequence which is complementary to at least two non-contiguous regions of an HBV nucleic acid, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                 /*tag= a

The present sequence represents a synthetic oligonucleotide HBV88Mb which is complementary to a portion of the hepatitis B virus (HBV) RNA. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides containing a sequence which is complementary to at least two non-contiguous regions of an HBV nucleic acid, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection
                                                                                                                                                                                                                                                                                                                                                                                                                                                                            a

The present invention describes a method of screening for an antiviral agent by the protein-priming activity of hepatitis B virus (HBV) DNA polymerase. Also described is developing an antiviral agent with a high selectivity to HBV which can be used for high-throughput screening. The present sequence represents an RNA oligonucleotide which is used in the exemplification of the present invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Single-stranded DNA probe comprising an anti-target nucleic acid, a (-)-promoter segment linked to the anti-target segment and a reporter segment, useful for detecting a target nucleic acid, e.g. hepatitis B
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          The present invention describes a single-stranded DNA probe (I) comprising in 3'-5' order, an anti-target nucleic acid segment, a (-)-promoter segment functionally linked to the anti-target segment, and a nucleic acid reporter segment. The probe is useful for testing a sample of a nucleic acid for the presence of a target nucleic acid for probe also be used for the detection of hepatitis B virus (HBV). The probe also be used for the detection of hepatitis B virus (HBV). The present which is used in an example from the present invention. (Updated on 15-
                                  Screening of antiviral agents by protein-priming activity of hepatitis virus DNA polymerase.

                                                                                                                                                                                                                                                                                                                                                                                                                                                          The present sequence represents a synthetic oligonucleotide HBV-87Mb which contains a sequence which is complementary to at least two noncontigonus regions of a hepatitis B virus (HBV) nucleic acid. The antisense oligonucleotide may be used to detect the presence of HBV in a sample. The antisense oligonucleotide, and oligonucleotides complementary to a portion of the HBV RNA, may be used for inhibiting HBV replication in a cell or for the treatment of HBV infection

```
The present invention relates to hepatitis B virus (HBV) strain FRI, genotype G DNA encoding PreCore/Core protein, HBpol, envelope (PreSI, preS2 and surface antigen HBBAG) and HBX proteins. HBV genotype G nucleic acids and surface artieful for diagnosing, prognosing and treating infections caused by HBV genotype G. They can be used in a vaccine to reat or prevent HBV genotype G infection. The HBV genotype G derived nucleic acids and antibodies are useful for detecting HBV genotype G in a sample or diagnosis of HBV genotype G infection. The presence of HBV genotype G infection. The presence of inver damage and/or liver cancer in the subject. The HBV genotype G core insert peptide encoding nucleic acid is useful for designing monitoring assays to study and predict the evolution of anti-HBe and anti-HBc antibodies and HBAG (genotype G e antigen) in patients infected with HBV. The antibodies or antigens of HBV genotype G are useful for identifying a stage of liver disease caused by HBV genotype G. The present sequence is a tagge of liver disease caused by HBV genotype G DNA fragment encoding e
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Novel hepatitis B virus genotype G, nucleic acids encoding virus, polypeptides encoded by nucleic acids, useful for preparing vaccine to treat or prevent the hepatitis B virus genotype G infection in a subject.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Zoulim F, Fried M;

AAD09093;

```
The present invention relates to hepatitis B virus (HBV) strain FR1,
genotype G DNA encoding PreCore/Core protein, HBpol, envelope (PreS1,
PreS2 and surface antigen HBAAG) and HBX proteins. HBV genotype G nucleic
acids and polypeprides are useful for diagnosing, prognosing and treating
infections caused by HBV genotype G. They can be used in a vaccine to
infections caused by HBV genotype G infection. The HBV genotype G derived
nucleic acids and antibodies are useful for detecting HBV genotype G in a
sample or diagnosis of HBV genotype G infection. The presence of HBV
genotype G statistically correlates with the presence of liver damage
cond/or liver cancer in the subject. The HBV genotype G core insert
petide encoding nucleic acid is useful for designing monitoring assays
to study and predict the evolution of anti-HBe and anti-HBc antibodies
and HBAAG (genotype G e antigen) in patients infected with HBV. The
antibodies or antigens of HBV genotype G are useful for identifying a
stage of liver disease caused by HBV genotype G. The present sequence is
a tage of liver disease caused by HBV genotype G DNA fragment
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Novel hepatitis B virus genotype G, nucleic acids encoding virus, polypeptides encoded by nucleic acids, useful for preparing vaccine to treat or prevent the hepatitis B virus genotype G infection in a subject.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        100.0%; Score 20; DB 4; Length 129; 100.0%; Pred. New nucleic acid regulatory sequences, which are able to regulate expression of a gene operably linked to a promoter, useful for regulating the expression of transgenes and for treating e.g., cancer and immunological diseases.

Disclosure, Fig 1A; 95pp; English.

The invention describes an isolated nucleic acid regulatory sequence for a cyclin D1 promoter, a CD40L promoter, vancomycin-resistant enterococci (VRE) promoter, an HBV promoter, andragon receptor (AR) promoter, Human epidermal growth factor receptor 2 (HBR2) promoter, or a beta lactamase (Bla) promoter. Transcription regulatory sequences may be used to regulate expression of the endogenous, autologous or heterologous genes operably linked to the promoter, and may be incorporated into heterologous nucleic acid constructs for use in regulated expression of transgenes. Regulated expression of cyclin D1 can be used in cancer therapies, such as breast, colon or pancreatic cancers and familial adenomatous polyposis. Regulation of the activity of CD40L gene promoter may be used in the treatment of immunological disorders, such as autoimmune diseases e.g. multiple solerosis (MS), systematic lupus erythematosus (SLE), graft, ve-host disease (GVHD) and rheumatoid

New proteins comprising a modified hepatitis B core antigen, useful as a vaccine in prophylactic or therapeutic vaccination of the human or animal body, particularly against hepatitis B virus infection.

Disclosure; Page 38-39; 40pp; English.

The invention relates to modified proteins comprising hepatitis B virus (HBV) core antigen (HBCAg) wherein one or more of the four arginine repeats has been deleted and the protein comprising the C-terminal cysteine of HBCAg. The deleted region may be replaced by an epitope from a protein other than HBCAg, in which case the HBCAg acts as a carrier to

arthritis. Regulated expression of genes under the control of the HBV (hepatitis B)-specific core, pre-S and X promoters can be used in the therapy of HBV disease, chronic hepatic insufficiancy, cirrhosis, hepatocellular carcinoma, and in the regulated expression of liver specific genes. Regulated expression of the vanH gene promoter can be used in treatment of Enterococcus infection, while regulated expression of the androgen receptor gene can be used in the treatment of prostate cancer. This sequence represents the hepatitis B virus core promoter the regulatory regions of which are described in the method of the invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                             Hepatitis B virus; HBV; core antigen; HBCAg; immune system; typhoid; prophylactic; gene therapy; vaccine; hepatitis A virus; HAV; herpes; hepatitis C virus; HCV; influenza; foot-and-mouth disease; diarrhoea; tuberculosis; polio; rabies; acquired immunodeficiency syndrome; AIDS; dengue fever; yellow fever; malaria; whooping cough; salmonellosis; food poisoning; meningitis; gonorrhea; antiviral; antibacterial;

          therapeutic acid is useful as a vaccine or in a method of prophylactic or therapeutic vaccination of the human or animal body, particularly against HBV. The nucleic acid encoding the protein may be used in gene therapy or DNA vaccination protocols. The chimeric protein or its nucleic acid may also be used as the basis of a prophylactic vaccine against a range of diseases, e.g. HBV, hepatitis A virus (HAV), hepatitis C virus (HCV), influenza, foot-and-mouth disease, polio, herpes, rabies, acquired immunodeficiency syndrome (AIDS), dengue fever, yellow fever malaria, tuberculosis, whooping cough, salmonallosis, typhoid, food poisoning, diarrhoea, meningitis or genorrhea. The present sequence is a DNA encoding Hepatitis B virus core antigen (HBCAG)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Hepatitis B (HB) core antigen fusion proteins, useful as vaccines for the prophylactic or therapeutic treatment of humans or animals against e.g. HB virus, viral hepatitis, hepatitis C virus, influenza, or foot-and-
present the epitope to the immune system. This chimeric protein or its

```

The present invention relates to hepatitis B virus (HBV) core antigen

```
ö
(HBCAg) fusion proteins and polynucleotides encoding such proteins. Sequences of the invention are useful in methods of prophylactic or therapeutic vaccination or to manufacture medicaments for prophylactic or therapeutic vaccination of the human or animal body against HBV, e.g. against viral hepatitis. They are also useful as a prophylactic vaccine against viral hepatitis. They are also useful as a prophylactic vaccine against e.g. hepatitis or virus, influenca, pollo, herpes, rables, acquired immune deficiency syndrome (AIDS) or foot-and-mouth disease. The present sequence is a DNA encoding hepatitis B virus core antigen (HBCAg)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Introducing nucleic acid molecules to an animal or human, useful for treating diseases including cancer, genetic diseases, arthritis or AIDS comprises administering a composition comprising two or more gene
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The invention relates to a method of introducing nucleic acid molecules to an animal which comprises administering a composition comprising two or more gene delivery vehicles to an animal at the same time and same site via a single administration device. The method is useful for introducing nucleic acid molecules to an animal, preferably humans for

containing the entire precore/core region, into the BamHI site of KSII+. The precore/core region of plasmid KSII+HBpc/p was sequenced and was found to contain a single base pair deletion which causes a frameshift at codon 79 which results in two consecutive in-frame TAG codons. This deletion was corrected by PCR overlap extension in plasmid SK+ HBe using mutation may also be corrected using the primers given in AAQ47019-23 in a separate series of reactions. The isolated HBV precore/core region may therapeutic cytotoxic T-lymphocyte (TID) response, and a humoral response for the treatment of hepatitis B and C infections, as well as hepatocellular carcinomas. treating diseases including cancer, genetic diseases, arthritis or AIDS.
The method can also be administered to plants using traditional methods.
The introduction of multiple or more than one nucleic acid molecule at one time provide significant advantages because multiple nucleic acid molecules can provide complementary substances or activities to a single corgan or joint. The difficulty, cost and time to engineer multiple corgan or joint. The difficulty, cost and time to engineer multiple nucleic acid molecules is much less than engineering a single molecule. With the use of multiple molecules, there is less chance that one substance or activity will sterically hinder or otherwise interfere with the use of multiple molecules or activities also permits the expression of different substances or activities from expression systems subject to differing activating events, thus permitting better control of differential expression of the different substances or activities. The present sequence represents the HBV precore/core DNA.
                                                                                                                                                                                                                                                                                                                ö

04-FEB-1993; 04-FEB-1992; This sequence represents the entire precore/core coding region of hepatitis B virus (HBV) isolated from the plasmid KSII+HBpc/c. This plasmid was created by ligating a 1.8 kb fragment of plasmid pAM6

Example 2; Fig 2; 110pp; English.

antigen.

```
antigen. The GDVs can be used in the method of the invention, for introducing nucleic acids into an animal, by administration of a composition comprising two or more GDVs, in combination with a carrier or diluent. Each GDV contains a nucleic acid molecule not naturally contained within the GDV, or directs expression of at least one substance (or biologically active nucleic acid) in host cells containing the GDV. The two GDVs collectively direct the expression of at least two different substances, or direct the expression of at least one substance, where the GDVs differ in one or more biological functions. The GDVs can be used for destroying hepatitis C carcinoma cells, for treating HBV (when a GDV contains an immunogenic HBV fragment such as this sequence). The GDVs can be used for directing expression of non-tumourigenic, tumour associated antigens (such as altered ras gene), altered p53 gene, and altered mucin. (Updated on 27-AUG-2003 to correct OS field.)
(GDV) of the invention, and is used as an immunogenic portion of a HBV

Novel isolated and/or purified hepatitis B virus polypeptide and polynucleotide sequences that are phylogenetically different from HBV genotype A-F molecules, useful for HBV diagnosis, prophylaxis and therapy

Claim 3; Fig 7; 94pp; English.

The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Burope and the USA. The invention relates to a fully defined sequence of 3248 nucleotides as given in sequence with 32% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polynucleotides are useful for HBV genotyping. The proteins encoded by

The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Europe and the USA. The invention relates to a fully defined sequence of 3248 mucleotides as given in specification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polymucleotides are useful for HBV genotyping. The proteins encoded by the polymucleotides are useful for detecting antibodies in a biological sample. Ligands that bind to the proteins and antibodies directed against the proteins are useful for detecting the proteins and for detecting the proteins and should gain the proteins are useful for detecting the proteins and for detecting the proteins and surface against the proteins are useful for detecting the proteins and for detecting the proteins are also useful for preparing a vaccine or medicament for treating HBV infections. The present sequence is provided in an alignment of precore/Core sequences of an HBV genotype A strain (HBVXCPS) and 7 strains (FRI, FRZ, USI, US3,

the invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Europe and the USA. The invention relates to a fully defined sequence of 3248 nucleotides as given in specification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polynucleotides are useful for HBW genotyping. The proteins encoded by the polynucleotides are useful for detecting antibodies directed against the proteins are useful for the proteins and antibodies directed against the proteins are useful for detecting the proteins and for detecting the proteins and vaccine or medicament for treating HBV infections. The present sequence is provided in an alignment of preCore/Core sequences of an HBV genotype A strain (HBVXCPS) and 7 strains (FRI, FRZ, USI, US3, US3, US3, US3, US3).

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Burope and the USA. The invention relates to a fully defined sequence of 3248 nucleotides as given in specification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polynucleotides are useful for HBV genotyping. The proteins encoded by the polynucleotides are useful for detecting antibodies in a biological sample. Ligands that bind to the proteins and antibodies directed against the proteins are useful for detecting the proteins and for detecting the proteins and for detecting HBCAg and HBCAg (precore precursor proteins). They are also useful for preparing a vaccine or medicament for treating HBV infections. The
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    present sequence is provided in an alignment of preCore/Core sequences of an HBV genotype A strain (HBVXCPS) and 7 strains (FR1, FR2, US1, US3, US6, US7, US9, US10) of HBV genotype G
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Novel isolated and/or purified hepatitis B virus polypeptide and polynucleotide sequences that are phylogenetically different from HBV genotype A-F molecules, useful for HBV diagnosis, prophylaxis and

The present invention relates to a method for treating hepatitis B or C directs the expression of at least one immunogenic portion of hepatitis B virus (HBV) antigen, containing HBeAg, HbcAg, HbsAg, S, Pre-S1, Pre-S2, open reading frame (ORF) 5, ORF 6, HBV pol or HBxAg or co-expression of a HBV antigen and at least one immunogenic portion of a HBV antigen and at least one immunogenic portion of a hepatitis C virus (HCV) antigen. The vectors are useful in gene therapy, particularly for treating or preventing hepatitis F and hepatitis C infections, as well as hepatoccellular carcinomas (HCC). The present sequence is a PCR primer used for amplifying Hepatitis B virus adw strain precore/core mutant DNA.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  New vectors that direct the (co-)expression of one or more immunogenic portions of the hepatitis B or C virus antigen(s), useful in gene therapy, e.g. for treating or preventing hepatitis B or C infections, or hepatocellular carcinomas.

Treating hepatitis C infections in a warm-blooded animal by administering a vector construct, which directs the expression of an immunogenic portion of a hepatitis C antigen, and alternatively, with an

immunomodulatory cofactor.

```
The invention relates to a method for treating hepatitis C infections in directs the expression of at least one immunogenic portion of a hepatitis C antigen, where an immune response is generated, and alternatively, in combination with an immunomodulatory cofactor. The invention also relates in a vector construct which directs the co-expression of at least one immunogenic portion of a hepatitis B antigen and at least one immunogenic portion of a hepatitis B antigen and the postion of the polyprotein antigen, an immunogenic portion of the polyprotein antigen, an immunogenic portion of the polyprotein antigen and an immunosegulatory cofactor. A recombinant virus carrying the vector construct is selected from poliovirus, rhinovirus, pox virus, canary pox virus, vaccinia virus, adenovirus, adenovirus, andenovirus, carrying the vector virus, vaccinia virus, adenovirus, and and an immunogenia with a virus, adenovirus, carrying the vector virus, vaccinia virus, adenovirus, and virus, adenovirus, and virus, and virus, adenovirus, and virus, and vir
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ;

The method is useful for treating intracellular infections or diseases including viral infections (e.g. hepatitis B virus (HBV), hepatitis C virus (HCV), herpes simplex virus (HSV), human immunodeficiency virus (HIV) or feline immunodeficiency virus (FIV)), parasitic infections (e.g. rickettsia, leishmaniasis or malaria) and certain bacterial diseases (e.g. legionella, tuberculosis or chlamydia). This sequence represents hepatitis B virus DNA used in the method of the

The coding sequences of the preC and C Ags of HB virus were inserted into Autograph californica nuclear polyhedrosis virus (AcNPV) transfer vector Autograph californica nuclear polyhedrosis virus (AcNPV) transfer vector and ACVANIXTO and PACYMIXTO and pACYMIXTO and pACYMIXTO cannot the Callowing cotransfection with infectious ACNPV DNA, recombinant baculoviruses were obtained - YMIXYC and YMIXYC. It was determined that all the HBCAG and HBpCAG was cell associated and that the yield of purified HBCAG was of the order of 5 mg per liter of 1x10(9) infected cells. Such Ag may be useful in vaccines. (Updated on 25-MAR-2003 to correct PR field.)

The invention relates to the complete nucleic acid sequence of a new human hepatitis B virus (HBV) genotype, provisionally named genotype G. This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Europe and the USA. The invention is pacification, a sequence of 3248 nucleotides as given in sequence. The patient is degenerate to the mentioned sequence. These polynucleotides are useful for HBV genotyping. The proteins encoded by sample. Ligands that bind to the proteins and antibodies directed against the polynucleotides are useful for detecting antibodies directed against the proteins are useful for detecting antibodies directed against the proteins are useful for detecting the proteins and subshape of the proteins and antibodies directed against the proteins are useful for detecting the proteins are useful for medicament for treating HBV infections. The preparing a vaccine or medicament for treating HBV infections. The present sequence is provided in an alignment of precore/Core sequences of an HBV genotype A strain (HBVXCPS) and 7 strains (FRI, FRZ, USI, US3, US7, US9, USIO) of HBV genotype G

The present sequence is the DNA sequence of the hepatitis B virus core antigen (HBcAg) gene from HBV serotype ayw. A peptide comprising a HBV protein can be used in claimed methods of the invention for modulating an immune response in a mammal. A method of inducing a systemic immune response to a peptide in a mammal comprises transmucosally administering for the hammal a macromolecular aggregate of the peptide. The macromolecular aggregate comprises at least 10 peptide subunits, may have a molecular weight of over 1,000 kba, and is preferably at least 5 nm in diameter. It is resistant to digestive degradation, being stabilised in aggregate form by chemical treatment and/or by recombinant protein caggregate form hy chemical treatment and/or by recombinant protein or engineering of the peptide. The peptide preferably comprises a HBV comprises and HBV surface protein, nucleocapsid protein or engineering of the mammal. A method of suppressing an immune response in the mammal. A method of suppressing an immune response in the mammal. A method of suppressing an immune response in the mammal. A method of suppressing an immune response in the mammal. A method of suppressing an immune response in the mammal. A method of suppressing an immune response in the mammal and which may be stabilised by that is resistant to digestive degradation and which may be stabilised by contal tolerance when induction of systemic immunity is undesirable, e.g. in cases of chronic infections.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Modulating a systemic immune response to a peptide in a mammal comprises transmucosally administering a macromolecular aggregate of the peptide.

They can be used in a vaccine to revent HBV genotype G infection. The HBV genotype G derived nucleic acids and antibodies are useful for detecting HBV genotype G in ample or diagnosis of HBV genotype G infection. The presence of HBV camped and/or liver cancer in the subject. The HBV genotype G core insert peptide encoding nucleic acid is useful for designing monitoring assays to study and predict the evolution of anti-HBc and anti-HBc antibodies and HBeAg (genotype G e antigen) in patients infected with HBV. The antibodies or antigens of HBV genotype G are useful for identifying a
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Novel hepatitis B virus genotype G, nucleic acids encoding virus, polypeptides encoded by nucleic acids, useful for preparing vaccine to treat or prevent the hepatitis B virus genotype G infection in a subject.

This genotype was found with a high prevalence in patients chronically infected with HBV and residing in Europe and the USA. The invention relates to a fully defined sequence of 3348 nucleotides as given in specification, a sequence with 92% identity to the given sequence, or sequence that is degenerate to the mentioned sequences. These polynucleotides are useful for they genotyping. The proteshs encoded by the polynucleotides are useful for detecting antibodies in a biological sample. Ligands that bind to the proteins and antibodies directed against the proteins are useful for detecting the proteins and for detecting the proteins and succeeding antibodies directed against the proteins are useful for detecting the proteins and succeeding the proteins and succeeding and the proteins and succeeding an accine or medicament for treating HBV infections. The present sequence is the complete coding sequence of the HBV preCore/Core
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Novel isolated and/or purified hepatitis B virus polypeptide and polynucleotide sequences that are phylogenetically different from HBV genotype A-F molecules, useful for HBV diagnosis, prophylaxis and

                                                                                                                                                                                                                                                                                                                                                                                                                                                             ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Regulatory and coding region of the X15 component in the X-myc construct.
                                                                                                                                                                                                                                                                                       The cloned HBV DNA can be used to engineer plasmids for HBcAg synthesis in bacteria. The DNA may be fused to a gene for beta galactosidase. The recombinant protein can be used for immuno- assays, to raise antibodies, and in vaccines. See also AAN82265 and 66. This polynucleotide represents the sequence of the regulatory and coding regions of the X15 component in the X-myc construct. The invention crastees to a bicistronic hepatitis B virus (HBW) X15-c-myc transgene, comprising of the HBV X15 gene and c-myc gene. The myc gene is known to be an activatable oncogene. The transgene encodes a truncated HBV X15 crotein, that has amino acids 58-154 of HBV X15 and a murine c-myc protein, respectively. A transgenic mouse containing the transgene construct is useful for screening a candidate substance (CS), to construct is useful for screening a candidate substance (CS), to construct by exposing a transgenic containing the transgene containing the mouse determined by exposing a transgenic couse to CS, and monitoring the mouse conformation to hepatocellular carcinoma in the transgenic mouse or to CS compared to the development of hepatocellular carcinoma in a conformation of the conformation of hepatocellular carcinoma in the conformation of hepatocellular carcinoma in the conformation of the carcinoma in the ca
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       for cell and tissue culture. The transgenic animal models comprising of the HBV X15-c-myc transgene for hepatocellular carcinoma are superior to any transgenic animal model system for hepatocellular carcinoma in that the transgenic animal model system for hepatocellular carcinoma in that the transgenic unice develop more aggressive and accelerated onset of malignant liver tumours in all lobes causing death of the affected animals in 20-22 weeks, that is faster than the time taken by the other transgenic animals to even develop a tumour
                                                                                                                                                                                                                                                         New bicistronic hepatitis B virus (HBV) X15-c-myc transgene, useful for producing transgenic mouse model systems for human hepatocellular carcinoma, comprises HBV X15 transgene and c-myc transgene.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Fulminant hepatitis B virus; variant; FHBV; HBV; binding interaction;

The present sequence represents part of the genome of a fulminant
Hepatitis B virus (FHBV) genotype D variant, nucleotides 1000 to 2500.
The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the cambrace a mutation from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative required region, the enhancer II force upstream regulatory sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the peptide amino acid change to Cys or Met. The HBV variants of the proteins and HBV nucleic acid. Probes that hybridise to any of the proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.
Specified mutated regions are used to detect HBV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions are used to detect BV-related disease.
Specified mutated regions BV-related BV-related BV-related BV-related BV-related BV-related BV-related BV-related BV-rel
                                                                  New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Fulminant hepatitis B virus genotype D variant FHBV5 sequence.

nucleic acid that has
             a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to P) in at least two of the enhancer I region, the negative regulatory element region, the enhancer II (core upstream regulatory sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cyg or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, sepecially fulminant infection, but also severe chronic infection or serologically unusual forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     The present sequence represents part of the genome of a fulminant Hepatitis B virus (FHBV) genotype D variant, nucleotides 1000 to 2500. The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, the enhancer II/ core upstream regulatory sequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV-related disease, especially fulminant infection, but also severe chronic infection or serologically unusual forms of disease. Combinations of the specified
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Fulminant hepatitis B virus; variant; FHBV; HBV; binding interaction; HBV-related disease; ss.
                                                                                                                                                                                                                                                                                                                                                                                            Gaps

B virus; variant; FHBV; HBV; binding interaction;

98WO-EP002048.

New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.

WPI; 1999-009329/01.

Carman B;

The present sequence represents part of the genome of a fulminant Hepatitis B virus (FHBV) genotype D variant, nucleotides 1000 to 2500.

The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory element region, the enhancer II/ core upstream regulatory pequence/ basal core promoter region, or a mutation which leads to an X-peptide amino acid change to Cys or Met. The HBV variants of the invention are used to detect binding interactions between host or viral proteins and HBV nucleic acid. Probes that hybridise to any of the process and mutated regions are used to detect HBV-related disease,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.
mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host cell
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            especially fulminant infection, but also severe chronic infection or serologically unusual forms of disease. Combinations of the specified mutations are associated with fulminant infections, probably because they reduce the ability to bind inhibitory proteins in the host call

The specification describes Hepatitis B virus (HBV) nucleic acid that has a mutation (i.e. alteration from the normal nucleotide in any of the genotypes A to F) in at least two of the enhancer I region, the negative regulatory selement region, the enhancer II ore upstream regulatory sequence/ basal core promoter region, or a mutation which leads to peptide amino acid change to Cys or Met. The HBV variants of the proteins and HBV nucleic acid. Probes that hybridise to any of the specified mutated regions are used to detect HBV related disease.
                                                                                                                                                                                                                                                                                                                                                                                                          New hepatitis B virus nucleic acid with combination of specific mutations - useful for, e.g. detection of binding interactions between host or viral proteins and HBV nucleic.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                probably because they

The present sequence represents part of the genome of a fulminant

The present sequence represents part of the genome of a fulminant

The specification describes Hepatitis B virus (HBV) nucleic acid that has

a mutation (i.e. alteration from the normal nucleotide in any of the

genotypes A to F) in at least two of the enhancer I region, the negative

regulatory element region, the enhancer II region, the negative

credulatory alement region, the enhancer II region, the negative

credulatory alement region, the enhancer of the

peptide amino acid change to (ys or Met. The HBV variants of the

proteins and HBV nucleic acid. Probes that hybridise to any of the

proteins and HBV nucleic acid. Probes that hybridise to any of the

specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.

Specified mutated regions are used to detect HBV-related disease.
